## Midterm Answers

1. a. In the Cobb-Douglas production function, $\mathrm{Q}=\mathrm{AK}^{\square} \mathrm{L}^{\square}$, the elasticity of output with respect to capital is a and the elasticity of output with respect to labor is b . Here, with $\mathrm{a}=0.4, \mathrm{a} 1 \%$ increase in K increases Q by $0.4 \%$ and a $5 \%$ increase in K increases Q by $5(0.4)=2.0 \%$.
b. The percentage change in $\mathrm{X} / \mathrm{Y}$ is approximately equal to the percentage change in X minus the percentage change in Y. Here, if K increases by $3 \%$ and L increases by $4 \%$, the approximate percentage change in $\mathrm{K} / \mathrm{L}$ is $3 \%-4 \%=-1 \%$.
c. The percentage change in XY is approximately equal to the percentage change in X plus the percentage change in Y. Here, if P increases by $5 \%$ and Q falls by $4 \%$, the approximate percentage change in PQ is $5 \%$ $+(-4 \%)=1 \%$.
d. The percentage change in $\mathrm{Q}[\mathrm{K}, \mathrm{L}]$ is approximately equal to the elasticity of Q with respect to K multiplied by the percentage change in K , plus the elasticity of Q with respect to L multiplied by the percentage change in L. Here, as in part a, the elasticities are 0.4 and 0.6 and the approximate percentage increase in Q is $0.4(5 \%)+0.6(5 \%)=5 \%$. More generally if the elasticities add to 1 , then the CobbDouglas production function exhibits constant returns to scale in that an $\mathrm{x} \%$ change in all inputs will increase output by $\mathrm{x} \%$.
2. a. Taking the partical derivative:

$$
\frac{\partial V}{\partial R}=\frac{\square D}{(R \square g)^{2}}
$$

Thus the elasticity is

$$
\begin{aligned}
\square & =\left|\frac{\partial \mathrm{V}}{\partial \mathrm{R}} \frac{\mathrm{~V}}{\mathrm{~V}}\right| \\
& =\frac{\square \mathrm{D}}{\square(\mathrm{R} \square \mathrm{~g})^{2}} \mathrm{D} \frac{\mathrm{R}}{\mathrm{D} /(\mathrm{R} \square \mathrm{~g})} \\
& =\frac{\mathrm{R}}{\mathrm{R} \square \mathrm{~g}}
\end{aligned}
$$

b. The partical derivative of the elasticity with respect to $g$ is positive

$$
\frac{\partial \square}{\partial g}=\frac{R}{(R \square g)^{2}}>0
$$

Thus the value of a growth stock is more sensitive to changes in R .
3.a. Holding Y constant, the first derivative of utility with respect to X is

$$
\frac{\partial U}{\partial X}=\frac{3}{X}>0(\text { positive } \operatorname{marg} \text { inal utility })
$$

b. Holding Y constant, the second derivative of utility with respect to X is

$$
\frac{\partial^{2} U}{\partial X^{2}}=\square \frac{3}{X^{2}}<0 \text { (diminishing marg inal utility) }
$$

c. Taking the total derivative, we find that the slope of the indifference curve is negative:

$$
\begin{aligned}
\mathrm{U}_{0} & =3 \ln [\mathrm{X}]+\ln [\mathrm{Y}] \\
\mathrm{dU}_{0} & =\frac{\partial \mathrm{U}}{\partial \mathrm{X}} \mathrm{dX}+\frac{\partial \mathrm{U}}{\partial \mathrm{Y}} \mathrm{dY} \\
0 & =\frac{3}{\mathrm{X}} \mathrm{dX}+\frac{1}{\mathrm{Y}} \mathrm{dY} \\
\frac{\mathrm{dY}}{\mathrm{dX}} & =\square 3 \frac{\mathrm{Y}}{\mathrm{X}}=\square 3 \text { at } \mathrm{X}=\mathrm{Y}
\end{aligned}
$$

d. The negative slope of the indifference curve means that if this person obtains more $X$, utility will not be constant unless this person has less Y. The first derivative gives the terms at which this person is willing to trade Y for X . For example, at $\mathrm{X}=\mathrm{Y}, \mathrm{dY} / \mathrm{dX}=-3$ means that this person is willing to trade 3 units of Y for 1 unit of $X$.
4. a. The profit function is

$$
\begin{aligned}
\square & =\mathrm{PQ} \square \mathrm{C} \\
& =\mathrm{H}^{7500 \mathrm{Q}^{\square 0.5}-\mathrm{R} \square 100 \mathrm{Q}^{1.5}} \\
& =7500 \mathrm{Q}^{0.5} \square 100 \mathrm{Q}^{1.5}
\end{aligned}
$$

The first and second derivatives are

$$
\begin{aligned}
\square & =\mathrm{PQ} \square \mathrm{C} \\
& =7500 \mathrm{Q}^{0.5} \square 100 \mathrm{Q}^{1.5} \\
\frac{\mathrm{~d} \square}{\mathrm{dQ}} & =3750 \mathrm{Q}^{\square 0.5} \square 150 \mathrm{Q}^{0.5}=0 \text { at } \mathrm{Q}=25 \\
\frac{\mathrm{~d}^{2} \square}{\mathrm{dQ}^{2}} & =\square 1875 \mathrm{Q}^{\square 1.5} \square 75 \mathrm{Q}^{\square 0.5}<0
\end{aligned}
$$

The negative second derivative tells us that $\mathrm{Q}=25$ is a maximum.
b. Marginal cost is

$$
\frac{\mathrm{dC}}{\mathrm{dQ}}=150 \mathrm{Q}^{0.5}=750
$$

c. Marginal revenue is:

$$
\frac{\mathrm{d}(\mathrm{PQ})}{\mathrm{dQ}}=3750 \mathrm{Q}^{\square 0.5}=750 \text { at } \mathrm{Q}=25
$$

d. Marginal revenue is equal to marginal cost at the profit-maximizing output, because the level of output can only be profit-maximizing if producing more does not increase revenue more than it increases cost and if producing less does not decrease revenue less than it decreases cost; that is, only if marginal revenue is equal to marginal cost.
5. a. The net present value is

$$
\begin{aligned}
\mathrm{P}[\mathrm{t}] & =\mathrm{V}[\mathrm{t}] \mathrm{e}^{\square \mathrm{Rt}} \square \mathrm{C} \\
& =100 \mathrm{t}^{0.9} \mathrm{e}^{\square 0.05 \mathrm{t}} \square 50
\end{aligned}
$$

b. We can set the first derivative equal to zero:

$$
\begin{aligned}
\frac{d P[t]}{d t} & =100 \mathrm{t}^{0.9} \mathrm{e}^{\square 0.05 \mathrm{t}}(\square 0.05)+0.9(100) \mathrm{t}^{\square 0.1} \mathrm{e}^{\square 0.05 \mathrm{t}} \\
& =\square 5 \mathrm{t}^{0.9} \mathrm{e}^{\square 0.05 \mathrm{t}}+90 \mathrm{t}^{\square 0.1} \mathrm{e}^{\square 0.05 \mathrm{t}} \\
& =\mathrm{e}^{\square 0.05 \mathrm{t}} \mathrm{~B}^{-10 t^{\square 0.1}} \square 5 \mathrm{t}^{0.9} \\
& =0 \text { when } \\
\mathrm{t} & =\frac{90}{5}=18
\end{aligned}
$$

c. The second derivative is negative (indicating a maximum):

$$
\begin{aligned}
\frac{\mathrm{dP}[\mathrm{t}]}{\mathrm{dt}} & =\mathrm{e}^{\square 0.05 \mathrm{t}} \mathrm{~B}^{\circ} 9 \mathrm{t}^{\square 0.1} \square 5 \mathrm{t}^{0.9} \mathrm{R} \\
\frac{\mathrm{~d}^{2} \mathrm{P}[\mathrm{t}]}{\mathrm{dt}^{2}} & \left.=\square 0.05 \mathrm{e}^{\square 0.05 \mathrm{t}} \mathrm{~B}^{\circ} 9 \mathrm{t}^{\square 0.1} \square 5 \mathrm{t}^{0.9} \mathrm{H}+\mathrm{e}^{\square 0.05 \mathrm{t}} \mathrm{H}\right] 9 \mathrm{t}^{\square 1.1} \square 4.5 \mathrm{t}^{\square 0.1} \\
& <0 \text { at } \frac{\mathrm{dP}[\mathrm{t}]}{\mathrm{dt}}=0
\end{aligned}
$$

d. In general, the differentiation of $\mathrm{P}[\mathrm{t}]$ with respect to t shows that $\mathrm{W}^{\prime}[\mathrm{t}]=0$ when $\mathrm{V}^{\prime}[\mathrm{t}] / \mathrm{V}[\mathrm{t}]=\mathrm{R}$, that is, the rate of change of the harvest value is equal to the real interest rate:

$$
\begin{aligned}
\mathrm{P}[\mathrm{t}] & =\mathrm{V}[\mathrm{t}] \mathrm{e}^{\square \mathrm{Rt}} \square \mathrm{C} \\
\frac{\mathrm{dP}[\mathrm{t}]}{\mathrm{dt}} & =\mathrm{V}[\mathrm{t}] \mathrm{e}^{\square \mathrm{Rt}}(\square \mathrm{R})+\mathrm{V}[\mathrm{t}] \mathrm{e}^{\square \mathrm{Rt}} \\
& =0 \text { when } \\
\frac{\mathrm{V}[\mathrm{t}]}{\mathrm{V}[\mathrm{t}]} & =\mathrm{R}
\end{aligned}
$$

Thus the trees should be kept growing as long as the increase in the value of the stand is larger than the interest rate.
